YANG Data Model for a "Keystore" Mechanism
draft-ietf-netconf-keystore-03

Abstract

This document defines a YANG module for a system-level mechanism, called a "keystore", containing security-sensitive data including private keys, pinned certificates, and pinned SSH host-keys.

Editorial Note (To be removed by RFC Editor)

This draft contains many placeholder values that need to be replaced with finalized values at the time of publication. This note summarizes all of the substitutions that are needed. No other RFC Editor instructions are specified elsewhere in this document.

Artwork in this document contains shorthand references to drafts in progress. Please apply the following replacements:

- "VVVV" --> the assigned RFC value for this draft

Artwork in this document contains placeholder values for the date of publication of this draft. Please apply the following replacement:

- "2017-10-18" --> the publication date of this draft

The following Appendix section is to be removed prior to publication:

- Appendix A. Change Log

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at https://datatracker.ietf.org/drafts/current/.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any
time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 20, 2018.

1. Introduction

This document defines a YANG [RFC7950] module for a system-level mechanism, herein called a "keystore". The keystore provides a centralized location for security sensitive data, as described below.

This module has the following characteristics:

- A configurable list of keys, each a public/private key pair. If a key is used to sign a certificate signing request (CSR), which is then signed by a certificate authority (CA), then the resulting certificate may be configured as being associated with the key. Keys are expected to be configured using standard configuration mechanisms, however, to support hardware that generates keys, the key may also be created via an action called ‘generate-private-key" action. Keys may also be preinstalled (e.g., a key associated to an IDevID [Std-802.1AR-2009] certificate).

- An unordered list of pinned certificate sets, where each pinned certificate set contains an unordered list of pinned certificates. This structure enables a server to use specific sets of pinned certificates on a case-by-case basis. For instance, one set of pinned certificates might be used by an HTTPS-client when connecting to particular HTTPS servers, while another set of pinned certificates might be used by a server when authenticating client connections (e.g., certificate-based client authentication).

- An unordered list of pinned SSH host key sets, where each pinned SSH host key set contains an unordered list of pinned SSH host keys. This enables a server to use specific sets of pinned SSH host keys on a case-by-case basis. For instance, SSH clients can be configured to use different sets of pinned SSH host keys when connecting to different SSH servers.

- An action to request the server to generate a new key using the specified algorithm. The resulting key is present in <operational>.

- An action to request the server to generate a certificate signing request for an existing key. Passed into the action are the subject and attributes to be used, and returned is the CSR (certificate signing request) structure, signed by the key protected by the keystore. The CSR can be signed by an external certificate authority (CA). The signed certificate returned by the CA can be associated with the key in the keystore, using a standard configuration operation (<edit-config>).
- A notification to indicate when a certificate is about to expire.

Special consideration has been given for systems that have Trusted Protection Modules (TPMs). These systems are unique in that the TPM must be directed to generate new keys (it is not possible to load a key into a TPM) and it is not possible to backup/restore the TPM's private keys as configuration.

It is not required that a system has an operating system level keystore utility to implement this module.

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119] [RFC8174] when, and only when, they appear in all capitals, as shown here.

1.2. Tree Diagram Notation

A simplified graphical representation of the data models is used in this document. The meaning of the symbols in these diagrams is as follows:

- Brackets "[" and "]" enclose list keys.
- Braces "{" and "}" enclose feature names, and indicate that the named feature must be present for the subtree to be present.
- Abbreviations before data node names: "rw" means configuration (read-write) and "ro" state data (read-only).
- Symbols after data node names: "?" means an optional node, "!" means a presence container, and "*" denotes a list and leaf-list.
- Parentheses enclose choice and case nodes, and case nodes are also marked with a colon (":”).
- Ellipses ("...") stands for contents of subtrees that are not shown.

2. Design Considerations

This document uses PKCS #10 [RFC2986] for the "generate-certificate-signing-request" action. The use of Certificate Request Message Format (CRMF) [RFC4211] was considered, but it was unclear if there was market demand for it, and so support for CRMF has been left out
of this specification. If it is desired to support CRMF in the future, placing a "choice" statement in both the input and output statements, along with an "if-feature" statement on the CRMF option, would enable a backwards compatible solution.

In order to use YANG identities for algorithm identifiers, only the most commonly used RSA key lengths are supported for the RSA algorithm. Additional key lengths can be defined in another module or added into a future version of this document.

This document limits the number of elliptical curves supported. This was done to match industry trends and IETF best practice (e.g., matching work being done in TLS 1.3). If additional algorithms are needed, they can be defined by another module or added into a future version of this document.

For the trusted-certificates list, Trust Anchor Format [RFC5914] was evaluated and deemed inappropriate due to this document’s need to also support pinning. That is, pinning a client-certificate to support NETCONF over TLS client authentication.

3. Tree Diagram

The keystore module has the following tree diagram. Please see Section 1.2 for information on how to interpret this diagram.
module: ietf-keystore
  +--rw keystore
    +--rw keys
      +--rw key* [name]
        +--rw name string
        +--rw algorithm identityref
        +--rw private-key union
        +--rw public-key binary
      +--rw certificates
        +--rw certificate* [name]
          +--rw name string
          +--rw value? binary
        +--x generate-certificate-signing-request
          +--w input
            +--w subject binary
            +--w attributes? binary
          +--ro output
            +--ro certificate-signing-request binary
        +--x generate-private-key
          +--w input
            +--w name string
            +--w algorithm identityref
      +--rw pinned-certificates* [name]
        +--rw name string

        +--rw pinned-certificate* [name]
          +--rw name string
          +--rw data binary
      +--rw pinned-host-keys* [name]
        +--rw name string
        +--rw description? string
        +--rw pinned-host-key* [name]
          +--rw name string
          +--rw data binary

notifications:
  +--n certificate-expiration
    +--ro certificate instance-identifier
    +--ro expiration-date yang:date-and-time

4. Example Usage

The following example illustrates what a fully configured keystore might look like. This keystore has three keys, four sets of trusted certificates, and one set of trusted host keys.

<keystore xmlns="urn:ietf:params:xml:ns:yang:ietf-keystore"/>
<!-- private keys and associated certificates -->
<keys>
  <key>
    <name>ex-rsa-key</name>
    <algorithm>rsa1024</algorithm>
    <private-key>base64encodedvalue==</private-key>
    <public-key>base64encodedvalue==</public-key>
    <certificates>
      <certificate>
        <name>ex-rsa-cert</name>
        <value>base64encodedvalue==</value>
      </certificate>
    </certificates>
  </key>
  <key>
    <name>tls-ec-key</name>
    <algorithm>secp256r1</algorithm>
    <private-key>base64encodedvalue==</private-key>
    <public-key>base64encodedvalue==</public-key>
    <certificates>
      <certificate>
        <name>tls-ec-cert</name>
        <value>base64encodedvalue==</value>
      </certificate>
    </certificates>
  </key>
  <key>
    <name>tpm-protected-key</name>
    <algorithm>rsa2048</algorithm>
    <private-key>base64encodedvalue==</private-key>
    <public-key>base64encodedvalue==</public-key>
    <certificates>
      <certificate>
        <name>builtin-idevid-cert</name>
        <value>base64encodedvalue==</value>
      </certificate>
      <certificate>
        <name>my-1devid-cert</name>
        <value>base64encodedvalue==</value>
      </certificate>
    </certificates>
  </key>
</keys>

<!-- Manufacturer’s trust root CA certs -->
<pinned-certificates>
<name>manufacturers-root-ca-certs</name>
<description>
Certificates built into the device for authenticating manufacturer-signed objects, such as TLS server certificates, vouchers, etc.. Note, though listed here, these are not configurable; any attempt to do so will be denied.
</description>
<pinned-certificate>
  <name>Manufacturer Root CA cert 1</name>
  <data>base64encodedvalue==</data>
</pinned-certificate>
<pinned-certificate>
  <name>Manufacturer Root CA cert 2</name>
  <data>base64encodedvalue==</data>
</pinned-certificate>
</pinned-certificates>

</!-- pinned netconf/restconf client certificates -->
<pinned-certificates>
  <name>explicitly-trusted-client-certs</name>
  <description>
  Specific client authentication certificates for explicitly trusted clients. These are needed for client certificates that are not signed by a pinned CA.
  </description>
  <pinned-certificate>
    <name>George Jetson</name>
    <data>base64encodedvalue==</data>
  </pinned-certificate>
</pinned-certificates>

</!-- pinned netconf/restconf server certificates -->
<pinned-certificates>
  <name>explicitly-trusted-server-certs</name>
  <description>
  Specific server authentication certificates for explicitly trusted servers. These are needed for server certificates that are not signed by a pinned CA.
  </description>
  <pinned-certificate>
    <name>Fred Flintstone</name>
    <data>base64encodedvalue==</data>
  </pinned-certificate>
</pinned-certificates>

</!-- trust anchors (CA certs) for authenticating clients -->
<pinned-certificates>
  <name>deployment-specific-ca-certs</name>
</pinned-certificates>
<description>
Trust anchors (i.e. CA certs) that are used to authenticate client connections. Clients are authenticated if their certificate has a chain of trust to one of these configured CA certificates.
</description>
<pinned-certificate>
  <name>ca.example.com</name>
  <data>base64encodedvalue==</data>
</pinned-certificate>
</pinned-certificates>

<!-- trust anchors for random HTTPS servers on Internet -->
<pinned-certificates>
  <name>common-ca-certs</name>
  <description>
  Trusted certificates to authenticate common HTTPS servers. These certificates are similar to those that might be shipped with a web browser.
  </description>
  <pinned-certificate>
    <name>ex-certificate-authority</name>
    <data>base64encodedvalue==</data>
  </pinned-certificate>
</pinned-certificates>

<!-- pinned SSH host keys -->
<pinned-host-keys>
  <name>explicitly-trusted-ssh-host-keys</name>
  <description>
  Trusted SSH host keys used to authenticate SSH servers. These host keys would be analogous to those stored in a known_hosts file in OpenSSH.
  </description>
  <pinned-host-key>
    <name>corp-fw1</name>
    <data>base64encodedvalue==</data>
  </pinned-host-key>
</pinned-host-keys>
</keystore>

The following example illustrates the "generate-certificate-signing-request" action in use with the NETCONF protocol.
REQUEST
-------
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action xmlns="urn:ietf:params:xml:ns:yang:1">
    <keystore xmlns="urn:ietf:params:xml:ns:yang:ietf-keystore">
      <keys>
        <key>
          <name>ex-key-sect571r1</name>
          <generate-certificate-signing-request>
            <subject>base64encodedvalue==</subject>
            <attributes>base64encodedvalue==</attributes>
          </generate-certificate-signing-request>
        </key>
      </keys>
    </keystore>
  </action>
</rpc>

RESPONSE
--------
<rpc-reply message-id="101">
  <certificate-signing-request
    xmlns="urn:ietf:params:xml:ns:yang:ietf-keystore">
    base64encodedvalue==
  </certificate-signing-request>
</rpc-reply>

The following example illustrates the "generate-private-key" action in use with the NETCONF protocol.
The following example illustrates the "certificate-expiration" notification in use with the NETCONF protocol.

This YANG module imports modules defined in [RFC6536] and [RFC6991]. This module uses data types defined in [RFC2315], [RFC2986], [RFC3447], [RFC4253], [RFC5280], [RFC5915], and [ITU.X690.1994]. This module uses algorithms defined in [RFC3447] and [RFC5480].

6. Security Considerations

The YANG module defined in this document is designed to be accessed via YANG based management protocols, such as NETCONF [RFC6241] and RESTCONF [RFC8040]. Both of these protocols have mandatory-to-implement secure transport layers (e.g., SSH, TLS) with mutual authentication.

The NETCONF access control model (NACM) [RFC6536] provides the means to restrict access for particular users to a pre-configured subset of all available protocol operations and content.

There are a number of data nodes defined in this YANG module that are writable/creatable/deletable (i.e., config true, which is the default). These data nodes may be considered sensitive or vulnerable in some network environments. Write operations (e.g., edit-config) to these data nodes without proper protection can have a negative effect on network operations. These are the subtrees and data nodes and their sensitivity/vulnerability:

/ : The entire data tree defined by this module is sensitive to write operations. For instance, the addition or removal of keys, certificates, trusted anchors, etc., can dramatically alter the implemented security policy. This being the case, the top-level node in this module is marked with the NACM value 'default-deny-write'.

/keystore/keys/key/private-key: When writing this node, implementations MUST ensure that the strength of the key being configured is not greater than the strength of the underlying secure transport connection over which it is communicated. Implementations SHOULD fail the write-request if ever the strength of the private key is greater then the strength of the underlying transport, and alert the client that the strength of the key may have been compromised. Additionally, when deleting this node, implementations SHOULD automatically (without explicit request) zeroize these keys in the most secure manner.
available, so as to prevent the remnants of their persisted storage locations from being analyzed in any meaningful way.

Some of the readable data nodes in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control read access (e.g., via get, get-config, or notification) to these data nodes. These are the subtrees and data nodes and their sensitivity/vulnerability:

/keystore/keys/key/private-key: This node is additionally sensitive to read operations such that, in normal use cases, it should never be returned to a client. The best reason for returning this node is to support backup/restore type workflows. This being the case, this node is marked with the NACM value ‘default-deny-all’.

Some of the operations in this YANG module may be considered sensitive or vulnerable in some network environments. It is thus important to control access to these operations. These are the operations and their sensitivity/vulnerability:

generate-certificate-signing-request: For this action, it is RECOMMENDED that implementations assert channel binding [RFC5056], so as to ensure that the application layer that sent the request is the same as the device authenticated when the secure transport layer was established.

7. IANA Considerations

7.1. The IETF XML Registry

This document registers one URI in the IETF XML registry [RFC3688]. Following the format in [RFC3688], the following registration is requested:

Registrant Contact: The NETCONF WG of the IETF.
XML: N/A, the requested URI is an XML namespace.

7.2. The YANG Module Names Registry

This document registers one YANG module in the YANG Module Names registry [RFC6020]. Following the format in [RFC6020], the following registration is requested:
8. Acknowledgements

The authors would like to thank for following for lively discussions on list and in the halls (ordered by last name): Andy Bierman, Martin Bjorklund, Benoit Claise, Mehmet Ersue, Balazs Kovacs, David Lamparter, Alan Luchuk, Ladislav Lhotka, Radek Krejci, Tom Petch, Juergen Schoenwaelder; Phil Shafer, Sean Turner, and Bert Wijnen.

9.1. Normative References

9.2. Informative References

Appendix A. Change Log

A.1. server-model-09 to 00

- This draft was split out from draft-ietf-netconf-server-model-09.
- Removed key-usage parameter from generate-private-key action.
- Now /private-keys/private-key/certificates/certificate/name must be globally unique (unique across all private keys).
- Added top-level 'trusted-ssh-host-keys' and 'user-auth-credentials' to support SSH client modules.

A.2. keychain-00 to keystore-00

- Renamed module from "keychain" to "keystore" (Issue #3)

A.3. 00 to 01

- Replaced the 'certificate-chain' structures with PKCS#7 structures. (Issue #1)
- Added 'private-key' as a configurable data node, and removed the 'generate-private-key' and 'load-private-key' actions. (Issue #2)
- Moved 'user-auth-credentials' to the ietf-ssh-client module. (Issues #4 and #5)

A.4. 01 to 02

- Added back 'generate-private-key' action.
- Removed 'RESTRICTED' enum from the 'private-key' leaf type.
- Fixed up a few description statements.

A.5. 02 to 03

- Changed draft’s title.
- Added missing references.
- Collapsed sections and levels.
- Added RFC 8174 to Requirements Language Section.
- Renamed 'trusted-certificates' to 'pinned-certificates'.
o Changed ‘public-key’ from config false to config true.

o Switched ‘host-key’ from OneAsymmetricKey to definition from RFC 4253.
